

Raw vegetables and fruit 'counteract heart risk genes'

People who are genetically susceptible to heart disease can lower their risk by eating plenty of fruit and raw vegetables, a study suggests.

Experts already recommend eating at least five portions of fruit and veg a day for good health

It says five or more daily portions should be enough to counteract culprit versions of a gene on chromosome 9, thought to be possessed by a fifth of people of European ancestry.

Healthy diets appeared to weaken its effect.

The Canadian researchers investigated more than 27,000 people for their work.

The findings were published in *Plos Medicine* journal.

These participants came from around the globe, including Europe, China and Latin

America.

The results suggest that individuals with high risk 9p21 gene variants who consumed a diet packed with raw vegetables, fruits and berries had a similar risk of heart attack as those with a low-risk variant of the same gene.

Researcher Prof Sonia Anand, of McMaster University, said: "Our results support the public health recommendation to consume more than five servings of fruits or vegetables as a way to promote good health."

The scientists, who also included staff from McGill University, say they now need to do more work to establish how diet might have this effect on genes.

Judy O'Sullivan of the British Heart Foundation said the findings should serve as a reminder that while lifestyle and genes could increase heart risk, the way the two interacted with each other was
